SYRINGA MOBILE HOME PARK (PWS 2290038) SOURCE WATER ASSESSMENT DRAFT REPORT

September 27, 2001

State of Idaho Department of Environmental Quality

Disclaimer: This publication has been developed as part of an informational service for the source water assessments of public water systems in Idaho and is based on the data available at the time and the professional judgement of the staff. Although reasonable efforts have been made to present accurate information, no guarantees, including expressed or implied warranties of any kind, are made with respect to this publication by the State of Idaho or any of its agencies, employees, or agents, who also assume no legal responsibility for the accuracy of presentations, comments, or other information in this publication. The assessment is subject to modification if new data is produced.

Executive Summary

Under the Safe Drinking Water Act Amendments of 1996, all states are required by the U.S. Environmental Protection Agency to assess every source of public drinking water for its relative sensitivity to contaminants regulated by the act. This assessment is based on a land use inventory of the designated assessment area, sensitivity factors associated with the wells, and aquifer characteristics.

This report, *Source Water Assessment for Syringa Mobile Home Park*, describes the public drinking water system, the boundaries of the zones of water contribution, and the associated potential contaminant sources located within these boundaries. This assessment should be used as a planning tool, taken into account with local knowledge and concerns, to develop and implement appropriate protection measures for this source. **The results should not be used as an absolute measure of risk and they should not be used to undermine public confidence in the water system.**

The Syringa Mobile Home Park drinking water system consists of seven wells situated in the crystalline rock aquifer approximately three miles east of Moscow. Wells 1 and 3 are backup wells. Wells 2, 4, 7, 8 and 10 supply water to three reservoirs and two pressurized tanks on a regular basis. A review of the State drinking water sampling data (DWIMS) indicates that in 1999 and 2000 there have been two events where repeated sampling found total coliform microbial contamination in the systems manifold system. Water in the manifold system is derived from all of the active wells, which makes it impossible to determine if the contamination is coming from any single well or from the delivery system downstream of each well. The source of microbial contamination should be determined and eliminated. There has been a single detection of the inorganic contaminant (IOC) nitrate but at levels below maximum contaminant level (MCL). In 1993 there were two trace detections of a synthetic organic contaminant (SOC) pesticide but no further detections since then. There are no recorded detections of volatile organic contaminants (VOC) like petroleum products. Other practices aimed at reducing the leaching of chemicals from agricultural land within the designated source water areas should be implemented.

This assessment should be used as a basis for determining appropriate new protection measures or re-evaluating existing protection efforts. No matter what ranking a source receives, protection is always important. Whether the source is currently located in a "pristine" area or an area with numerous industrial and/or agricultural land uses that require education and surveillance, the way to ensure good water quality in the future is to act now to protect valuable water supply resources.

Most of the designated areas are outside the direct jurisdiction of the Syringa Mobile Home Park. Partnerships with state and local agencies and industry groups should be established and are critical to success. Due to the time involved with the movement of ground water, source water protection activities should be aimed at long-term management strategies even though these strategies may not yield results in the near term. Source water protection activities for agriculture should be coordinated with the Idaho State Department of Agriculture, the Soil Conservation Commission, the local Soil Conservation District, and the Natural Resources Conservation Service.

A community with a fully developed source water protection program will incorporate many strategies. For assistance in developing protection strategies please contact the Lewiston Regional Office of the Idaho Department of Environmental Quality or the Idaho Rural Water Association.

SOURCE WATER ASSESSMENT FOR HIDDEN VILLAGE MOBILE HOME PARK, LATAH COUNTY, IDAHO

Section 1. Introduction - Basis for Assessment

The following sections contain information necessary to understand how and why this assessment was conducted. It is important to review this information to understand what the ranking of this source means. A map showing the delineated source water assessment area and the inventory of significant potential sources of contamination identified within that area are attached. The list of significant potential contaminant source categories and their rankings, used to develop this assessment, is also attached.

Level of Accuracy and Purpose of the Assessment

The Idaho Department of Environmental Quality (DEQ) is required by the U.S. Environmental Protection Agency (EPA) to assess the over 2,900 public drinking water sources in Idaho for their relative susceptibility to contaminants regulated by the Safe Drinking Water Act. This assessment is based on a land use inventory of the delineated assessment area, sensitivity factors associated with the wells, and aquifer characteristics. All assessments must be completed by May of 2003. The resources and time available to accomplish assessments are limited. Therefore, an in-depth, site-specific investigation to identify each significant potential source of contamination for every public water system is not possible. This assessment should be used as a planning tool, taken into account with local knowledge and concerns, to develop and implement appropriate protection measures for this source. The results should not be used as an absolute measure of risk and they should not be used to undermine public confidence in the water system.

The ultimate goal of this assessment is to provide data to local communities to develop a protection strategy for their drinking water supply system. The Idaho Department of Environmental Quality (DEQ) recognizes that pollution prevention activities generally require less time and money to implement than treating a public water supply system once it has been contaminated. DEQ encourages communities to balance resource protection with economic growth and development. The decision as to the amount and types of information necessary to develop a source water protection program should be determined by the local community based on its own needs and limitations. Wellhead or source water protection is one facet of a comprehensive growth plan, and it can complement ongoing local planning efforts.

Section 2. Conducting the Assessment

General Description of the Source Water Quality

The wells at Syringa Mobile Home Park are community wells with 100 connections serving 300 people. Syringa Mobile Home Park is located in Latah County, approximately 1.75 miles east-northeast of Moscow (Figure 1).

The only significant water chemistry problem recorded for the Syringa Mobile Home Park are two verified detections of microbials in composite samples taken in 1999 and 2000. Detections of microbials in drinking water constitute a serious threat to human health and should be dealt with. One verified detection of trace amounts of a SOC pesticide was found in 1993 with no subsequent detections. No detections of VOC have been recorded. There have been detections of nitrate, but at levels far below MCL.

Defining the Zones of Contribution--Delineation

The delineation process establishes the physical area around a well that will become the focal point of the assessment. The process includes mapping the boundaries of the zone of contribution into time of travel zones (zones indicating the number of years necessary for a particle of water to reach a well) for water in the aquifer. DEQ used a refined computer model approved by the EPA in determining the 3-year (Zone 1B), 6-year (Zone 2), and 10-year (Zone 3) time-of-travel (TOT) for water associated with the Crystalline rock aquifer in the vicinity of the Syringa Mobile Home Park. The computer model used site- specific data, assimilated by DEQ from a variety of sources including local area well logs. Wells at Syringa Mobile Home Park draw water from Precambrian metasediments within the geologic formation known as the Belt Supergroup. Groundwater flow in this aquifer tends to follow topography and often ranges from 15 to 100 feet deep. Hydrologic gradients may be very steep and highly irregular. Based on this information the delineation areas for the two Syringa Mobile Home Park wells are estimated to follow paths as depicted in Figures 2 through 8, Attachment A. The actual data used by DEQ in determining the source water assessment delineation areas is available upon request.

Identifying Potential Sources of Contamination

A potential source of contamination is defined as any facility or activity that stores, uses, or produces, as a product or by-product, the contaminants regulated under the Safe Drinking Water Act and has a sufficient likelihood of releasing such contaminants at levels that could pose a concern relative to drinking water sources. The goal of the inventory process is to locate and describe those facilities, land uses, and environmental conditions that are potential sources of ground water contamination. The locations of potential sources of contamination within the delineation areas were obtained by field surveys conducted by DEQ and from available databases. The dominant land use outside the Syringa Mobile Home Park is non-irrigated agricultural land and undeveloped rangeland. Land use within the immediate area of the wellheads consists of the mobile home park.

5

It is important to understand that a release may never occur from a potential source of contamination provided best management practices are used at the facility. Many potential sources of contamination are regulated at the federal level, state level, or both, to reduce the risk of release. Therefore, when a business, facility, or property is identified as a potential contaminant source, this should not be interpreted to mean that this business, facility, or property is in violation of any local, state, or federal environmental law or regulation. What it does mean is that the <u>potential</u> for contamination exists due to the nature of the business, industry, or operation. There are a number of methods that water systems can use to work cooperatively with potential sources of contamination, such as educational visits and inspections of stored materials. Many owners of such facilities may not even be aware that they are located near a public water supply well.

Contaminant Source Inventory Process

A two-phased contaminant inventory of the study area was conducted during May of 2000. The first phase involved identifying and documenting potential contaminant sources within the Syringa Mobile Home Park Source Water Assessment Area through the use of computer databases and Geographic Information System maps developed by DEQ. The second or enhanced phase of the contaminant inventory involved contacting the operator to validate the sources identified in phase one and to add any additional potential sources in the area.

Results of the inventory process indicate that there are no potential contaminant sites within the delineated source water areas for any of the seven water wells at Syringa Mobile Home Park (Figure 2). Contaminant sources looked for include IOCs, VOCs, SOCs and microbials. Although microbials have been detected, no obvious source was found during the contaminant inventory process. It is likely that the route of microbial contamination could be via one of the wellheads or it could have entered drinking water along the delivery system somewhere downstream of the wells. Since re-sampling also detected microbials it is highly unlikely that sampling error occurred. Figures 2 through 8 (Attachment A) depict the delineation zones for Wells 1, 2, 3, 4, 7, 8, and 10.

Section 3. Susceptibility Analyses

The water system's susceptibility to contamination was ranked as high, moderate, or low-risk according to the following considerations: hydrologic characteristics, physical integrity of the well, land use characteristics, and potentially significant contaminant sources. The susceptibility rankings are specific to a particular potential contaminant or category of contaminants. Therefore, a high susceptibility rating relative to one potential contaminant does not mean that the water system is at the same risk for all other potential contaminants. The relative ranking that is derived for each well is a qualitative, screening-level step that, in many cases, uses generalized assumptions and best professional judgement. The following summaries describe the rationale for the susceptibility ranking.

Hydrologic Sensitivity

At Syringa Mobile Home Park, hydrologic sensitivity risk rating is moderate for all seven wells (Table 1). All of the wellheads are collared in soils in the poor to moderately well drained class, which could facilitate the downward movement of contaminants. However, the well logs indicate that the local vadose zone below the soil contains some clay, which could ultimately retard downward movement of contaminants.

Well Construction

Well construction directly affects the ability of a well to protect the aquifer from contaminants. All of the wells at Syringa Mobile Home Park have a high-risk construction score. Although there are drill hole logs for each well and a 1994 sanitary survey of the system, there is no conformation that the wellhead seals are in good shape and protected from floodwaters. The well logs for each well indicates that recently up-graded Idaho Department of Water Resources casing thickness requirements are not being met. The Idaho Department of Water Resources Well *Construction Standards Rules* (1993) require all Public Water Systems (PWSs) to follow DEQ standards as well. IDAPA 58.01.08.550 requires that PWSs follow the *Recommended Standards for Water Works* (1997) during construction. Table 1 of the *Recommended Standards for Water Works* (1997) states that 8-inch casing requires a thickness of 0.322 inch and 6-inch casing requires a thickness of 0.280 inch. Although no apparent problems have been found associated with any of the wellheads, repeated microbial contamination in the system leaves the possibility that contamination could be entering drinking water via one or more of the wellheads.

Potential Contaminant Source and Land Use

The predominant land use in the area is non-irrigated agriculture, undeveloped rangeland and residential. The only significant water quality problem recorded from the Syringa Mobile Home Park water system that may be associated with local land use is multiple detections of total coliform microbial contamination. The contaminant entry route for microbial contamination could be along one of more of the well casings or it could have entered the system somewhere downstream of the wells. There are no recorded detections of inorganic contaminants (IOC) like metals. However, low levels of IOC nitrate has been found. There have been no detections of volatile organic contaminants (VOC) like petroleum products and no recent detections of synthetic organic contaminants (SOC) like pesticides.

Final Susceptibility Rating

The Syringa Mobile Home Park drinking water system has an overall high-risk rating for microbial contamination due to the verified detection of coliform bacteria in 1999 and again in 2000. No IOC (nitrate) detections above MCL and no recent detections of SOC or VOC contaminants have been recorded for the Syringa Mobile Home Park. All conditions combined result in an overall moderaterisk rating for potential contamination in IOC, VOC and SOC (Table 1).

Table 1. Summary of Syringa Mobile Home Park Susceptibility Evaluation

	Susceptibility Scores ¹

Section 4. Options for Source Water Protection

The susceptibility assessment should be used as a basis for determining appropriate new protection measures or re-evaluating existing protection efforts. No matter what the susceptibility ranking a source receives, protection is always important. Whether the source is currently located in a "pristine" area or an area with numerous industrial and/or agricultural land uses that require education and surveillance, the way to ensure good water quality in the future is to act now to protect valuable water supply resources.

An effective source water protection program is tailored to the particular local source water protection area. A community with a fully developed source water protection program will incorporate many strategies. The primary water quality issue currently facing Syringa Mobile Home Park is that of microbial contamination. Since 1999, there have been two verified detections of total coliform microbial contamination. Microbial contamination in drinking water is serious threat to human health. Efforts need to be made to determine where microbials are entering Syringa Mobile Home Park's drinking water system. If a source and route is found it should be eliminated. Most of the designated areas are outside the direct jurisdiction of the Syringa Mobile Home Park. Partnerships with state and local agricultural agencies and industry groups should be established and are critical to success. Due to the time involved with the movement of ground water, wellhead protection activities should be aimed at long-term management strategies even though these strategies may not yield results in the near term. Source water protection activities for agriculture should be coordinated with the Idaho State Department of Agriculture, the Soil Conservation Commission, the Soil and Water Conservation District, and the Natural Resources Conservation Service.

Assistance

Public water suppliers and others may call the following DEQ offices with questions about this assessment and to request assistance with developing and implementing a local protection plan. In addition, draft protection plans may be submitted to the DEQ office for preliminary review and comments.

Lewiston Regional DEO Office (208) 799-4370

State DEQ Office (208) 373-0502

Website: http://www2.state.id.us/deq

Water suppliers serving fewer than 10,000 persons may contact John Bokor, Idaho Rural Water Association, at 1-800-962-3257 for assistance with wellhead protection strategies.

POTENTIAL CONTAMINANT INVENTORY LIST OF ACRONYMS AND DEFINITIONS

<u>AST (Aboveground Storage Tanks)</u> – Sites with aboveground storage tanks.

<u>Business Mailing List</u> – This list contains potential contaminant sites identified through a yellow pages database search of standard industry codes (SIC).

<u>CERCLIS</u> – This includes sites considered for listing under the <u>Comprehensive Environmental Response Compensation and Liability Act (CERCLA)</u>. CERCLA, more commonly known as Superfund is designed to clean up hazardous waste sites that are on the national priority list (NPL).

<u>Cyanide Site</u> – DEQ permitted and known historical sites/facilities using cyanide.

<u>Dairy</u> – Sites included in the primary contaminant source inventory represent those facilities regulated by Idaho State Department of Agriculture (ISDA) and may range from a few head to several thousand head of milking cows.

<u>Deep Injection Well</u> – Injection wells regulated under the Idaho Department of Water Resources generally for the disposal of stormwater runoff or agricultural field drainage.

Enhanced Inventory – Enhanced inventory locations are potential contaminant source sites added by the water system. These can include new sites not captured during the primary contaminant inventory, or corrected locations for sites not properly located during the primary contaminant inventory. Enhanced inventory sites can also include miscellaneous sites added by the Idaho Department of Environmental Quality (DEQ) during the primary contaminant inventory.

Floodplain – This is a coverage of the 100year floodplains.

<u>Group 1 Sites</u> – These are sites that show elevated levels of contaminants and are not within the priority one areas.

<u>Inorganic Priority Area</u> – Priority one areas where greater than 25% of the wells/springs show constituents higher than primary standards or other health standards.

<u>Landfill</u> – Areas of open and closed municipal and non-municipal landfills.

<u>LUST (Leaking Underground Storage Tank)</u> – Potential contaminant source sites associated with leaking underground storage tanks as regulated under RCRA.

<u>Mines and Quarries</u> – Mines and quarries permitted through the Idaho Department of Lands.)

<u>Nitrate Priority Area</u> – Area where greater than 25% of wells/springs show nitrate values above 5mg/l.

NPDES (National Pollutant Discharge Elimination System) – Sites with NPDES permits. The Clean Water Act requires that any discharge of a pollutant to waters of the United States from a point source must be authorized by an NPDES permit.

<u>Organic Priority Areas</u> – These are any areas where greater than 25 % of wells/springs show levels greater than 1% of the primary standard or other health standards.

<u>Recharge Point</u> – This includes active, proposed, and possible recharge sites on the Snake River Plain.

RICRIS – Site regulated under **Resource Conservation Recovery Act (RCRA)**. RCRA is commonly associated with the cradle to grave management approach for generation, storage, and disposal of hazardous wastes.

SARA Tier II (Superfund Amendments and Reauthorization Act Tier II Facilities) – These sites store certain types and amounts of hazardous materials and must be identified under the Community Right to Know Act.

<u>Toxic Release Inventory (TRI)</u> – The toxic release inventory list was developed as part of the Emergency Planning and Community Right to Know (Community Right to Know) Act passed in 1986. The Community Right to Know Act requires the reporting of any release of a chemical found on the TRI list.

<u>UST (Underground Storage Tank)</u> – Potential contaminant source sites associated with underground storage tanks regulated as regulated under RCRA.

<u>Wastewater Land Applications Sites</u> – These are areas where the land application of municipal or industrial wastewater is permitted by DEQ.

<u>Wellheads</u> – These are drinking water well locations regulated under the Safe Drinking Water Act. They are not treated as potential contaminant sources.

NOTE: Many of the potential contaminant sources were located using a geocoding program where mailing addresses are used to locate a facility. Field verification of potential contaminant sources is an important element of an enhanced inventory.

Where possible, a list of potential contaminant sites unable to be located with geocoding will be provided to water systems to determine if the potential contaminant sources are located within the source water assessment area.

Attachment B

Syringa Mobile Home Park Susceptibility Analysis Worksheet

The final scores for the susceptibility analysis were determined using the following formulas:

- 1) VOC/SOC/IOC Final Score = Hydrologic Sensitivity + System Construction + (Potential Contaminant/Land Use x 0.2)
- 2) 2) Microbial Final Score = Hydrologic Sensitivity + System Construction + (Potential Contaminant/Land Use x 0.35)

Final Susceptibility Scoring:

- 0 5 Low Susceptibility
- 6 12 Moderate Susceptibility
- ≥ 13 High Susceptibility
